                            <1>     ; have to wait anymore by setting it's status from 2 to 1
                            <1>     ; (waiting to active). It is awakened and put on runq by
                            <1>     ; 'putlu'. The dying process enters a zombie state in which
                            <1>     ; it will never be run again but stays around until a 'wait'
                            <1>     ; is completed by it's parent process. If the parent is not
                            <1>     ; found, process just dies. This means 'swap' is called with
                            <1>     ; 'u.uno=0'. What this does is the 'wswap' is not called
```

```
                            <1>     ; to write out the process and 'rswap' reads the new process
                            <1>     ; over the one that dies..i.e., the dying process is
                            <1>     ; overwritten and destroyed.
                            <1>     ;
                            <1>     ; Calling sequence:

1199                            <1>     ; 24/05/2013 - 14/02/2014 (Retro UNIX 8086 v1)
1200                            <1>     ;
1201                            <1>     ; 'sysfork' creates a new process. This process is referred
1202                            <1>     ; to as the child process. This new process core image is
1203                            <1>     ; a copy of that of the caller of 'sysfork'. The only
1204                            <1>     ; distinction is the return location and the fact that (u.r0)
1205                            <1>     ; in the old process (parent) contains the process id (p.pid)
1206                            <1>     ; of the new process (child). This id is used by 'syswait'.
1207                            <1>     ; 'sysfork' works in the following manner:
1208                            <1>     ;    1) The process status table (p.stat) is searched to find
```

```
1209                                    <1>     ;       a process number that is unused. If none are found
1210                                    <1>     ;       an error occurs.
1211                                    <1>     ;    2) when one is found, it becomes the child process number
1212                                    <1>     ;       and it's status (p.stat) is set to active.
1213                                    <1>     ;    3) If the parent had a control tty, the interrupt
1214                                    <1>     ;       character in that tty buffer is cleared.
1215                                    <1>     ;    4) The child process is put on the lowest priority run
1216                                    <1>     ;       queue via 'putlu'.
1217                                    <1>     ;    5) A new process name is gotten from 'mpid' (actually
1218                                    <1>     ;       it is a unique number) and is put in the child's unique
1219                                    <1>     ;       identifier; process id (p.pid).
1220                                    <1>     ;    6) The process name of the parent is then obtained and
1221                                    <1>     ;       placed in the unique identifier of the parent process
1222                                    <1>     ;       name is then put in 'u.r0'.
1223                                    <1>     ;    7) The child process is then written out on disk by
1224                                    <1>     ;       'wswap',i.e., the parent process is copied onto disk
1225                                    <1>     ;       and the child is born. (The child process is written
1226                                    <1>     ;       out on disk/drum with 'u.uno' being the child process
1227                                    <1>     ;       number.)
1228                                    <1>     ;    8) The parent process number is then restored to 'u.uno'.
1229                                    <1>     ;    9) The child process name is put in 'u.r0'.
1230                                    <1>     ;   10) The pc on the stack sp + 18 is incremented by 2 to
1231                                    <1>     ;       create the return address for the parent process.
1232                                    <1>     ;   11) The 'u.fp' list as then searched to see what files
1233                                    <1>     ;       the parent has opened. For each file the parent has
1234                                    <1>     ;       opened, the corresponding 'fsp' entry must be updated
1235                                    <1>     ;       to indicate that the child process also has opened
1236                                    <1>     ;       the file. A branch to 'sysret' is then made.
1237                                    <1>     ;
1238                                    <1>     ; Calling sequence:
1239                                    <1>     ;       from shell ?
1240                                    <1>     ; Arguments:
